ACKNOWLEDGEMENTS

The authors wish to thank the individuals who served on the projections committee for their timely advice and valuable suggestions. The committee was comprised of the following individuals:

Linda Koenig, Association of Central Oklahoma Governments
Rich Brierre, Indian Nations Council of Government
Roger Jacks, Oklahoma Employment Security Commission
Dan Gorin, Oklahoma Department of Commerce
Tabitha Doescher, Office of Business and Economic Research,
Oklahoma State University
Craig Knutson, Southwestern Bell
Steve Hiebsch, Oklahoma Gas and Electric
Jim Clark, Grand Gateway Economic Development Association
Ed Crone, Eastern Oklahoma Development District
Don Blose, Oklahoma Department of Health
Roger Deapen, Oklahoma Department of Health

The authors also gratefully acknowledge the assistance provided by members of the Research and Planning staff. Sandy Arnold, Secretary in the Office of Economic and Policy Research, constructed the majority of the innumerable tables and prepared the text for publication. Vicki Ruston, Secretary in Demographic Research and Data Management, assisted in preparing tables. Jeff Wallace, Statistical Analyst in Data Dissemination, assisted in the preparation of the city projections and along with John McCraw, Statistical Analyst in Demographic Research, helped in proofreading and verifying the data in this report. Harley Lingerfelt, Research and Planning Division Director, offered his guidance and valuable suggestions throughout the projections process. Others who deserve credit for their computer assistance include Rex Warshell and Cassandra Cooper of the Financial and Administrative Services Division of the Department of Commerce.

POPULATION PROJECTIONS FOR OKLAHOMA AND ITS COUNTIES BY AGE AND SEX, AND FOR ITS CITIES: 1980-2010

INTRODUCTION

This report presents projections of the resident population of Oklahoma and its counties by age and sex for each five year period from 1985 to 2010. It also includes projections of city population totals for the same period. These projections supersede the previous state projections which were published in January, 1987 and represent the first set of age and sex specific projections at the county level produced by the Oklahoma Department of Commerce.

Since actual future population trends are unknown, the projections in this report should not be considered a prediction of the future. Rather, these projections, calculated under a specific set of assumptions, indicate the levels of population that would result if our assumptions about each population component hold true. The assumptions utilized in this report, which are outlined in detail below, generally assume a continuation of current trends.

Three series of projections were calculated for the state and counties under three different sets of migration assumptions - "high," "medium" and "low." The series of projections calculated under "high" migration assume atypically high rates of migration. Correspondingly, "medium" migration assumes a moderate gain from migration, while "low" migration posits no population gain at all from migration. For city population projections, only one migration assumption, medium, was used.

METHODOLOGY

STATE LEVEL PROJECTIONS

The state projections were made using a cohort-component projection model. With this method, each component of population change - births, deaths and net migration - is projected separately for each five-year birth cohort by sex. Algorithms were developed for the projection model using SAS (Statistical Analysis System).

The cohort-component method employs the following basic demographic formula:

$$P_1 = P_0 + B - D + NM^*$$

Where:

P_1 = Population at the end of the period
P_0 = Population at the beginning of the period
B = Births during the period
D = Deaths during the period
NM = Net migration

The model works in the following manner. For every five-year projection period, the base population, disaggregated by five-year age groups by sex, is "survived" to the next five-year period by applying the appropriate survival rates for each age and sex group. Next, net migrants by age and sex are added to the survived population, as is the population under age 5. This younger population is generated by applying age specific birth rates to the females of childbearing age and surviving the births over the five-year period.

Base Population

In the absence of reliable estimates of population by age and sex for 1985, these projections begin with the April 1, 1980 census population of Oklahoma. The five-year age groups were carried forward to July 1, 1980, by assuming an arithmetic growth rate. The extrapolated population was arranged according to the 1980 census age and sex distribution. This estimate of the July 1, 1980 population was then used as the base population in the projection model.

The population data in this report are for the resident population of the state. They include members of the Armed Forces where they reside on duty.

---

*The demographic formula actually uses inmigration less outmigration (IM - OM), however, our model uses the concept of net migration instead.

Projections of Births

Fertility has been declining in both Oklahoma and the United States during the past several decades, but the decline for Oklahoma is not as dramatic as for the nation (41 percent versus 47 percent). The total fertility rate* for Oklahoma has declined from 3,419 per 1,000 in 1960 to 2,370 in 1970 (Lingerfelt and Selland, *Demographic State of the State*, Oklahoma, 1984) and continued to decline during the period 1970 to 1981 from 2,370 to 1,991 (Wetrogan, 1986 Annual Meeting of Federal State Cooperative Programs for Population Projections, Handout No. 3). For these projections, we assumed that the total fertility rate for the 1979-1981 period, 1,991, would prevail between 1980 and 2000. For the years 2000 to 2010, we assumed a 5.5 percent decline in the total fertility rate to 1,881.

The actual measures of fertility used in the model are age specific birth rates for females aged 15 to 49. The rates used were calculated by dividing the number of births by age of mother during the period 1979-1981 by the 1980 appropriate female population (see Table A-3 for state fertility rates). In the model, these rates are applied to the projected number of females of childbearing age at the beginning of each five year projection period to obtain the number of births over the five-year period. The gender of births was determined by applying the usual assumption of 105 male births for every 100 female births. This process results in the projected population under age 5 as of July 1 for each five-year projection period.

Projections of Deaths

The expectation of life at birth for the population of Oklahoma improved significantly over the decade of the 1970s. Over the period from 1969-71 to 1979-81, life expectancy in Oklahoma improved from 67.4 years to 69.6 years for males and from 75.7 years to 77.8 years for females (U.S. Department of Health and Human Services, *Oklahoma Life Tables 1969-71 and 1979-81*).

However, without a major breakthrough in medical technology and/or major improvements in health practices by Oklahomans, we do not anticipate a similarly large gain over the next several decades, but rather expect only a slight improvement over the projection period.

Therefore, for the decade of the 1980s, we assumed a continuance of the mortality experience of 1979-81, which is reflected in the *1979-81 Complete Life Table for Oklahoma* (U.S. Department of Health and Human Services, 1986). We expect a minor improvement in expectation of life by 1990 and another slight improvement in the year 2000. Specifically, our mortality assumptions place life expectancy at birth for Oklahomans at 70.9 years for males and 79.6 years for females in the year 2000.

The data from the 1979-81 life table was used to calculate state survival rates for 1980 by age and sex. In the projection model, the base population by age and sex for each projection period was survived to the next five year period by applying the appropriate survival rates for each group. Male and female births were also survived according to their respective survival rates.

To calculate the actual survival rates to be used in the model for 1990 and 2000, we made the following assumptions. For 1990, we assumed the number of exact survivors for a particular age by adding, to the exact survivors of 1980, one-fourth of the arithmetic difference in the exact survivors between 1970 and 1980. For the year 2000 we added one-eighth of the difference between 1970 and 1980 exact survivors to the 1990 survivors. We assumed mortality for the period 2000 to 2010 would remain the same.

Projections of Net Migration

The only consistency in Oklahoma's recent migration history has been its unpredictability. During the period from 1950 to 1960, the state lost over 218,000 people, but in the following decade gained about 15,000 persons. During the oil boom period there was a large inflow of net migrants to the state. Oklahoma gained 165,300 persons in the five years between 1975 and 1980 and 200,700 between 1980 and 1983 (1980 Census of Population and Oklahoma Employment Security Commission, unpublished data).

However, because of the oil price decline and subsequent economic problems, the state has been losing population due to net migration since 1983. According to recent estimates, 140,000 more persons have left the state than have come to the state during the last four years, 1983-1987 (Oklahoma Employment Security Commission,

*The total fertility rate is a measure of the number of children 1,000 women would have if they experienced a given set of age-specific birth rates throughout their reproductive span.

unpublished data).

Because net migration has been such a significant determinant of the state's growth and migration patterns have been so irregular, this report provides three different sets of net migration assumptions - high, medium and low - each corresponding to general economic conditions in the state. The high net migration assumption can be expected only with a major economic recovery in the state. This assumption of 15,000 net migrants per year, approximately half of the actual annual net migration over the period 1975 to 1985, represents a very high level of sustained migration for the state.

Under the low assumption we assumed no net migration, that is, outmigration and inmigration will balance each other over the long run. Under this assumption, the economy of the state is expected to improve very little, although it will not worsen.

Under the medium migration assumption, net migration of 5,000 per year, the state would undergo moderate economic growth with some loss of dependence on the oil and gas sector. We expect this scenario to be the most probable of the three. However, users of these projections must decide which alternatives fit their own particular needs.

While actual migration over short periods of time may actually be much greater (or much less) than the annual amounts used under the three assumptions, it is impossible to estimate the timing of these periods of future rapid growth over a thirty year time span. Therefore, we are assuming a pattern of steady migration for the future, rather than the boom and bust cycles typically experienced in this state.

For use in the computer model, migration had to be expressed in terms of persons by age and sex. The following methods were used to calculate these net migration figures. First, the inmigrant and outmigrant figures for age groups 5-9 years and older were derived from the 1975 to 1980 county-to-county migration data file from the 1980 Census. The number of net migrants for 1975 to 1980 was then computed as the difference between inmigrants and outmigrants for each age group.

To derive the estimates for the age group 0-4, the child-woman ratios for both male and female children were computed using relevant data from the 1980 Census. These ratios were then applied to both inmigrant and outmigrant women aged 15 to 44; one-half of the resultant figure was used as an estimate of the number of net migrants under the age of five.

The total net migrants under each migration assumption were distributed according to the age-sex distribution of the net migrants of the 1975 to 1980 period. On the basis of the 1975 to 1980 migration experience, we assumed that 55 percent of the net migrants were males and 45 percent were females for each projection period. We also assumed that the migrants in each age group survived the five year projection period.

COUNTY LEVEL PROJECTIONS

The procedure used for county projections was similar to that developed for the state projections, in that a cohort-component projection model was utilized. But separate methods were developed to account for the peculiarities of projecting county populations. For example, the basic data series needed for the model, fertility, mortality and migration, had to be treated differently than in the state projections. In addition, several counties have "special" or large institutional populations that necessitate an alternative projection procedure. Finally, the projected county totals obtained from the model were adjusted to achieve consistency between state and county totals.

Base Population

The 1980 census population of each county by age and sex was used as the base population. The projected population of 1985 for each county was adjusted to the totals of the July 1, 1985 population estimates of total population (*Population Estimates*, Oklahoma Employment Security Commission, 1987).

Projections of Births

Because county fertility rates can be quite volatile from year to year, we chose to average the rates in the following manner. We first examined actual total fertility rates for each county for the three periods 1969-1971, 1978-1982 and 1983-1985. Next the counties were grouped by type of total fertility - high, medium and low - evidenced in these three periods. For each group of counties, we computed an average total fertility rate which we assumed would prevail between 1980 and 2000 for each county in that group. The average total fertility rates for the three groups used in the model are 2,223, 1,942 and 1,713. For the years between

2000 to 2010, we assumed that county total fertility rates would converge with the state rate (1,881).

The distribution of fertility for each county used in the model was based on the actual age specific birth rates for females aged 15 to 44 during the period 1978-1982 in each county. This distribution was applied to the total fertility rate of each age group to obtain the projected age specific birth rates for each county. In addition, the total births for each county were divided into male and female births under the usual assumption of 105 male births for every 100 female births.

Projections of Deaths

In the absence of complete life tables for individual counties, we used the state survival rates by age and sex for each county. We thus assumed that each county would have the same mortality experience as that of the state. In general, the mortality differential between county and state is insignificant.

Projections of Net Migration

Recent county migration trends were projected into the future in the model. After averaging migration over the last 15 years (1970-1985), we calculated each county's proportion of total state migration over the period. By applying these proportions to the high, medium and low state migration totals, we calculated each county's projected migration totals for each of the three scenarios. To calculate the county net migrants by age and sex, we assumed that the 1975 to 1980 age and sex distribution of the net migrants of each county (from the Census of Population, 1980) would prevail during the entire projection period.

In addition to this basic procedure, we made adjustments to specific counties that are economically depressed or high growth. We based these adjustments on recent trends in employment data from the Bureau of Economic Analysis and the Oklahoma Employment Security Commission, migration data from the Internal Revenue Service and residual migration from the current population estimates, as well as information from members of the Projections Committee.

Special Population

In a few counties, institutional population accounts for a substantial portion of the county population. This special population has a growth pattern unpredictable by the usual demographic formula, thereby necessitating a different approach. If the institutional population constituted over 5 percent of the total population and more than 5,000 persons, the county deserved special handling. Under this criteria, Cleveland and Payne counties with major universities and Comanche with a large military installation had substantial "special" populations.

In these three counties we projected the special population separately from the general population based on the following procedure. First, we estimated the size of this population by age and sex in 1985. Secondly, we made the assumption that the size of the special population for each county would remain the same throughout the projection period.

Because we could not get good data on the age by sex distribution of the dormitory student population, it was necessary to make estimates of this population in Payne and Cleveland counties based on the data that were available. Using the 1983 and 1985 Fall dormitory population at the University of Oklahoma, we estimated that 55 percent of dormitory population in Cleveland and Payne would be males, that 28 percent of males and 34 percent of females would be of ages 15 to 19 and that the remaining population would fall in the age group 20 to 24. For Comanche county, we assumed that the special population would be of ages 15 to 49 and they would have the same age and sex distribution as that of Fort Sill in 1980. See Table A-8 in the Appendix for the actual age by sex distribution of the special population in each of the three counties.

Adjustments

Projections of some counties were adjusted to reflect recent changes in natural increase, net migration and employment in those counties. Projected county totals under the medium series of projections were adjusted to the projected state totals under the same series. The 1985 projection was adjusted to the 1985 estimate (OESC, 1987) of total state and county population, but the age by sex distributions are projected. Therefore, the age groups from the 1985 projections do not equal similar age groups in the 1985 estimates.

CITY LEVEL PROJECTIONS

Cohort component is a good technique for projecting population at state and county levels. But it may

provide unreliable figures for city projections because cities in Oklahoma are relatively small and their growth patterns can be highly volatile. Moreover, the input data required to apply a cohort-component technique are generally unavailable at the city level.

Instead, we used a "share-of-growth" technique to project city growth. After examining growth patterns of cities between 1960 and 1985 (using census populations and 1985 population estimates), we prepared three projections using each city's share of its county's population growth during the periods 1960 to 1985, 1970 to 1985, and 1980 to 1985. We took the average of these three projections as the unadjusted projection for each city. We then adjusted city projections to the county projection totals under the medium migration assumption.

ROUNDING

The projections in some tables in this report have been rounded. Age by sex projections in Tables 3 and 4 were rounded to the nearest integer. In addition, the metropolitan statistical area totals in Table 1, the county totals in Table 2, and the city totals in Tables 5 and 6 have all been rounded according to the following rules. If a number is smaller than 25, an asterisk rather than a number is given; if a number (or the last two digits of a number) falls between 25 and 74, it is rounded to 50; and if a number is between 75 and 99, it is rounded to the nearest 100.

LIMITATIONS

These projections are unlikely to be free of error since potential error is introduced with every assumption of future demographic trends. If actual trends deviate from those used in this report, the projections will obviously prove to be inaccurate. In particular, projections of small areas (small counties and cities) are generally less reliable than those for larger areas. In addition, the farther in the future we project, the less reliable the projections may become. As usual, projections were based on the general assumption that there would be no disastrous war, widespread epidemic, major economic depression or similar catastrophe.

AVAILABILITY OF MORE DETAILED PROJECTIONS

This report provides state and county projections for specified age groups, 0-4, 5-14, 15-44, 45-64, 65+ and 18+, under the medium migration assumption. Complete projections by five year age groups over the period 1980-2010 under the low, medium and high assumptions are available for counties upon request. In addition, these projections are available, upon request, on diskette.

GLOSSARY

Age Specific Birth Rate	The number of births to women of a given age group per 1,000 women in that age group.
Age Specific Mortality Rate	The number of deaths of persons of a given age during a year per 1,000 persons of that same age.
Birth Cohort	A group of people born during the same period of time; for example, all those born between 1980 and 1985 represent a birth cohort.
Child-Woman Ratio	The number of children ages 0-4 per 1,000 women of childbearing age (15-49).
Exact Survivors	The number of persons living at the beginning of an indicated age interval out of the total number of births assumed as the radix of a life table.
Expectation of Life at Birth	The average number of years a newborn can be expected to live after birth.
Fertility	Actual birth performance (e.g., the number of live births) by a woman.
Inmigration	Migration to a specific place (into the State of Oklahoma).
Life Table	One form of combining mortality rates of a population at different ages into a single statistical model that measures the level of mortality of that population.
Migration	A form of geographic or spatial mobility involving a change of usual residence between clearly defined geographic units. In reference to state level projections, we are referring to persons moving into or out of the state.
Net Migration	The difference between inmigration and outmigration.
Outmigration	Migration from a specific place (away from the State of Oklahoma).
Survival Rate	Probability of surviving from one age group to the next age group (e.g., from ages 15-19 to ages 20-24).
Total Fertility Rate	The number of births 1,000 women would have if they experienced a given set of age-specific birth rates throughout their reproductive span.
